

Plan An Attack

What's Your Goal?

- My goal is money. I would attempt to deploy ransomware on The Grand Marina's reservation and payment systems, so operations are disrupted, and management feels pressured to pay to get everything back up and running. If this happens during peak season, the urgency to fix it quickly would make paying the ransom more likely as well.

What's your entry point?

- I would start with a phishing email sent to the staff (not guests). Specifically, I would target someone in management who regularly handles invoices and logs into internal systems. The email would look like it's from a trusted vendor and include a fake invoice or a link to a realistic login page.

What's your path from entry to goals?

- I'd send the phishing email during a busy time when employees are more inclined to click without overthinking.
- If and when someone enters their credentials, I'll capture them
- I'll use those credentials to access internal systems
- I'll scan the network to find higher-value systems such as payment processing or reservation databases.
- As long as the network isn't segmented well, I'd attempt to move from the initial account into other connected systems and look for ways to gain higher-level access.
- Once I gain enough access, I'd deploy ransomware to lock down critical systems and then demand payment in cryptocurrency to restore them.

What might stop you along the way?

- Multifactor authentication would make any stolen credentials useless
- Strong network segmentation would limit how far I would be able to move within the system after getting initial access.
- Real-time monitoring could flag any suspicious login behavior before I fully compromise the system.
